### Evolutionary Search Augmented with Domain Knowledge

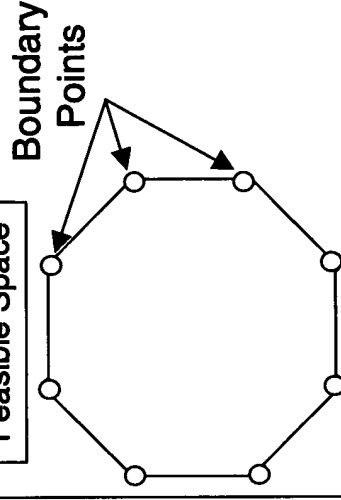

Multi-objective portfolio optimization problem is formulated as a problem with Multiple linear, nonlinear and nonlinear nonconvex objectives. However, the domain knowledge allows us to use strictly linear and convex constraints.

Linear Convex Feasible Space

Knowledge about geometry of feasible space (i.e. convexity), allowed us develop a feasible space boundary sampling algorithm (solutions archive generation). By knowing the boundary of the search space, we can exploit that knowledge to design efficient interior sampling methods.

Linear Convex Feasible Space

Convex crossover is a powerful interior sampling method, which is guaranteed to produce feasible offspring solutions. Given parents  $P_1$ ,  $P_2$ , it creates offspring  $O_1 = \lambda P_1 + (1 - \lambda)P_2$ ,  $O_2 = (1 - \lambda)P_1 + \lambda P_2$ . An offspring  $O_k$  and  $P_k$  can crossed over to produce more diverse offspring.
